Connections Between Inclusive and Exclusive Semileptonic B Decay[1]

Mark B. Wise

California Institute of Technology, Pasadena, CA 91125, USA[2]

Abstract. B decay sum rules relate exclusive B semileptonic decay matrix elements to forward B-meson matrix elements of operators in HQET. At leading order the operators that occur are the b-quark kinetic energy λ_1 and chromomagnetic energy λ_2. The latter is determined by the measured $B^* - B$ mass splitting. The derivation of these sum rules is reviewed and perturbative QCD corrections are discussed. A determination of λ_1 and the energy of the light degrees of freedom in a B-meson, $\bar{\Lambda}$, from semileptonic B decay data is presented. Future prospects for improving these sum rules are discussed.

I INTRODUCTION

In this lecture I review some connections between inclusive and exclusive semileptonic B-meson decays. These arise from sum rules that relate the form factors for exclusive semileptonic decays to nonperturbative QCD matrix elements that occur in the inclusive semileptonic decay rate. Sum rules that relate inclusive B transitions to a sum over exclusive states were first derived by Bjorken [1,2] and Voloshin [3]. Then a general framework for B-decay sum rules was presented by Bigi, et al. in [4]. Since this very important work, there has been a considerable amount of theoretical activity in the area of B decay sum rules [5–12].

For inclusive decays it is possible using the operator product expansion and a transition to the heavy quark effective theory (HQET) [13] to show that at leading order in $\Lambda_{\rm QCD}/m_b$ the B semileptonic decay rate is equal to the b-quark decay rate [14,15]. There are no nonperturbative corrections to this at order $\Lambda_{\rm QCD}/m_b$ [14]. The first corrections arise at order $\Lambda_{\rm QCD}^2/m_b^2$, and are

characterized by matrix elements [16] that are related to the b-quark kinetic energy

$$\lambda_1 = \frac{1}{2m_B}\langle B(v)|\bar{h}_v^{(b)}(iD)^2 h_v^{(b)}|B(v)\rangle, \tag{1}$$

and the color magnetic energy

$$\lambda_2 = \frac{1}{6m_B}\langle B(v)|\bar{h}_v^{(b)}\frac{g}{2}\sigma_{\mu\nu}G^{\mu\nu}h_v^{(b)}|B(v)\rangle. \tag{2}$$

The parameters λ_1 and λ_2 are independent of the heavy quark mass and occur in the formulas for the B, B^*, D, and D^* meson masses:

$$\begin{aligned} m_B &= m_b + \bar{\Lambda} - (\lambda_1 + 3\lambda_2)/2m_b, \\ m_{B^*} &= m_b + \bar{\Lambda} - (\lambda_1 - \lambda_2)/2m_b, \\ m_D &= m_c + \bar{\Lambda} - (\lambda_1 + 3\lambda_2)/2m_c, \\ m_{D^*} &= m_c + \bar{\Lambda} - (\lambda_1 - \lambda_2)/2m_c. \end{aligned} \tag{3}$$

The measured $B^* - B$ mass splitting $(46 \pm 0.6)\,\mathrm{MeV}$ implies that $\lambda_2 = 0.12\,\mathrm{GeV}^2$. The quantity $\bar{\Lambda}$ represents the energy of the light degrees of freedom for the ground state $s_\ell^{\pi_\ell} = \frac{1}{2}^-$ multiplet in the $m_{b,c} \to \infty$ limit. Note that in the average masses $\bar{m}_B = (m_B + 3m_{B^*})/4$ and $\bar{m}_D = (m_D + 3m_{D^*})/4$ the parameter λ_2 cancels out.

The leading order prediction of the operator product expansion for the B semileptonic decay rate involves quark masses, which are not known experimentally. What is measured are the hadron masses. It is possible using eq. (3) to express the quark masses, m_b and m_c, in terms of the hadron masses, $\bar{m}_B$ and $\bar{m}_D$, and the parameters λ_1 and $\bar{\Lambda}$. When this is done the semileptonic B-meson decay rate depends on the unknown parameters λ_1 and $\bar{\Lambda}$ that are of order $\Lambda_{\rm QCD}^2$ and $\Lambda_{\rm QCD}$ respectively. In this way of looking at the predicted decay rate there are contributions of order $\Lambda_{\rm QCD}/m_{c,b}$, but they are given in terms of the single parameter $\bar{\Lambda}$.

The form factors for semileptonic $B \to D^{(*)}e\bar{\nu}_e$ decay are defined by

$$\begin{aligned} \frac{\langle D(v')|V^\mu|B(v)\rangle}{\sqrt{m_B m_D}} &= h_+(w)(v+v')^\mu + h_-(w)(v-v')^\mu, \\ \frac{\langle D^*(v',\epsilon)|V^\mu|B(v)\rangle}{\sqrt{m_B m_{D^*}}} &= ih_V(w)\varepsilon^{\mu\nu\alpha\beta}\epsilon^*_\nu v'_\alpha v_\beta, \\ \frac{\langle D^*(v',\epsilon)|A^\mu|B(v)\rangle}{\sqrt{m_B m_{D^*}}} &= h_{A_1}(w)(w+1)\epsilon^{*\mu} - h_{A_2}(w)(\epsilon^*\cdot v)v^\mu \\ &\quad - h_{A_3}(w)(\epsilon^*\cdot v)v'^\mu. \end{aligned} \tag{4}$$

Here $V^\mu = \bar{c}\gamma^\mu b$ and $A^\mu = \bar{c}\gamma^\mu\gamma_5 b$ are the vector and axial vector currents. The four-velocities of the initial and final states are denoted by v and v'

respectively. The dot product of these four-velocities is $w = v \cdot v'$ and at the zero recoil point, where $v = v'$, $w = 1$. Up to corrections suppressed by powers of $\alpha_s(m_{c,b})$ and $\Lambda_{\rm QCD}/m_{c,b}$, $h_-(w) = h_{A_2}(w) = 0$ and $h_+(w) = h_V(w) = h_{A_1}(w) = h_{A_3}(w) = \xi(w)$, where the Isgur–Wise function [17] ξ is evaluated at a subtraction point around $m_{c,b}$. The differential decay rates are

$$\begin{aligned}
\frac{{\rm d}\Gamma(B \to D^* \ell \bar{\nu}_e)}{{\rm d}w} &= \frac{G_F^2 m_B^5}{48\pi^3} r^{*3} (1-r^*)^2 (w^2-1)^{1/2} (w+1)^2 \\
&\quad \times \left[1 + \frac{4w}{w+1} \frac{1 - 2wr^* + r^{*2}}{(1-r^*)^2}\right] |V_{cb}|^2 |\mathcal{F}_{B\to D^*}(w)|^2, \\
\frac{{\rm d}\Gamma(B \to D \ell \bar{\nu}_e)}{{\rm d}w} &= \frac{G_F^2 m_B^5}{48\pi^3} r^3 (1+r)^2 (w^2-1)^{3/2} |V_{cb}|^2 |\mathcal{F}_{B\to D}(w)|^2,
\end{aligned} \tag{5}$$

where $r^{(*)} = m_{D^{(*)}}/m_B$. The functions $\mathcal{F}_{B\to D^*}$ and $\mathcal{F}_{B\to D}$ are given in terms of the form factors of the vector and axial vector currents defined in eq. (4) as

$$\begin{aligned}
|\mathcal{F}_{B\to D^*}(w)|^2 &= \left[1 + \frac{4w}{w+1} \frac{1 - 2wr^* + r^{*2}}{(1-r^*)^2}\right]^{-1} \\
&\quad \times \left\{ \frac{1 - 2wr^* + r^{*2}}{(1-r^*)^2} 2 \left[h_{A_1}^2(w) + \frac{w-1}{w+1} h_V^2(w)\right] \right. \\
&\quad \left. + \left[h_{A_1}(w) + \frac{w-1}{1-r^*}\left(h_{A_1}(w) - h_{A_3}(w) - r^* h_{A_2}(w)\right)\right]^2 \right\}, \\
\mathcal{F}_{B\to D}(w) &= h_+(w) - \frac{1-r}{1+r} h_-(w).
\end{aligned} \tag{6}$$

Note that $\mathcal{F}_{B\to D^*}(1) = h_{A_1}(1)$ and due to Luke's theorem [18]

$$h_{A_1}(1) = \eta_A + \mathcal{O}(\Lambda_{\rm QCD}^2/m_{cb}^2). \tag{7}$$

For the $B \to D$ case $\mathcal{F}_{B\to D}(1) = \eta_V + \mathcal{O}(\Lambda_{\rm QCD}/m_{c,b})$. The quantities η_A and η_V relate the axial and vector currents in the full theory of QCD to those in HQET at zero recoil. Including corrections of order $\alpha_s^2\beta_0$ [19,20]

$$\begin{aligned}
\eta_A = 1 &- \frac{\alpha_s(\sqrt{m_b m_c})}{\pi} \left(\frac{1+z}{1-z} \ln z + \frac{8}{3}\right) \\
&- \frac{\alpha_s^2(\sqrt{m_b m_c})}{\pi^2} \beta_0 \frac{5}{24} \left(\frac{1+z}{1-z} \ln z + \frac{44}{15}\right),
\end{aligned} \tag{8}$$

where $z = m_c/m_b$ and $\beta_0 = 11 - 2N_f/3$ is the 1-loop beta function. In eq. (8) and hereafter dimensional regularization with $\overline{\rm MS}$ subtraction is used. The full order α_s^2 expression for η_A is known [21] and the $\alpha_s^2\beta_0$ part presented in eq. (8) dominates it.

II SUM RULES

To derive the sum rules, we consider the time-ordered product

$$T_{\mu\nu} = \frac{i}{2m_B} \int \mathrm{d}^4x\, e^{-iq\cdot x} \,\langle B \,|\, T\{J_\mu^\dagger(x), J_\nu(0)\}|B\,\rangle\,, \tag{9}$$

where J_μ is a $b \to c$ axial or vector current, the B states are at rest, $\vec{q}$ is fixed, and $q_0 = m_B - E_{D^{(*)}} - \epsilon$. Here $E_{D^{(*)}} = \sqrt{m_{D^{(*)}}^2 + |\vec{q}\,|^2}$ is the minimal possible energy of the hadronic final states that can be created by the current J_μ at fixed $|\vec{q}\,|$. (We deal with cases where the lowest energy state is either a D or a D^*.) With this definition of ϵ, $T_{\mu\nu}$ has a cut in in the complex ϵ plane that lies along $0 < \epsilon < \infty$, corresponding to physical intermediate states with a charm quark. At the same value of $|\vec{q}\,|$ the cut at the parton level lies in the smaller region $\epsilon > \bar{\Lambda}(w-1)/w + \mathcal{O}(\Lambda_{\rm QCD}^2/m_{c,b}^2)$, were $\vec{q}^{\,2} = m_c^2(w^2-1)$. $T_{\mu\nu}$ has another cut corresponding to physical states with two b-quarks and a $\bar{c}$ quark that lies along $-\infty < \epsilon < -2E_{D^{(*)}}$. To separate out specific hadronic form factors, one contracts the currents in eq. (9) with a suitably chosen four-vector a. Inserting a complete set of states between the currents yields

$$a^{*\mu}\, T_{\mu\nu}(\epsilon)\, a^\nu = \frac{1}{2m_B} \sum_X (2\pi)^3\, \delta^3(\vec{q} + \vec{p}_X)\, \frac{\langle B|J^\dagger\cdot a^*|X\rangle\langle X|J\cdot a|B\rangle}{E_X - E_{D^{(*)}} - \epsilon} + \dots\,, \tag{10}$$

where the ellipses denote the contribution from the cut corresponding to two b-quarks and a $\bar{c}$ quark. The sum over X includes the usual phase space factors, $\mathrm{d}^3p/(2\pi)^3 2E_X$, for each particle in the state X.

While $T_{\mu\nu}(\epsilon)$ cannot be computed for arbitrary values of ϵ, its integrals with appropriate weight functions are calculable using the operator product expansion and perturbative QCD. Consider integrating the product of a weight function $W_\Delta(\epsilon)$ with $T_{\mu\nu}(\epsilon)$ along the contour C surrounding the physical cut shown in Fig. 1. Assuming W is analytic in the shaded region enclosed by this contour, we get

$$\begin{aligned} &\frac{1}{2\pi i}\int_C \mathrm{d}\epsilon\, W_\Delta(\epsilon)\,[a^{*\mu}\, T_{\mu\nu}(\epsilon)\, a^\nu] \\ &\qquad = \sum_X W_\Delta(E_X - E_{D^{(*)}})\,(2\pi)^3\,\delta^3(\vec{q} + \vec{p}_X)\,\frac{|\langle X|J\cdot a|B\rangle|^2}{2m_B}\,. \end{aligned} \tag{11}$$

The weight function is assumed to be positive along the cut and to satisfy the normalization condition $W_\Delta(0) = 1$. Then $W_\Delta \cdot |\langle X|J\cdot a|B\rangle|^2$ is positive for all states X, and eq. (11) implies an upper bound on the magnitude of form factors for semileptonic B decays to the ground states $D^{(*)}$.

$$\frac{|\langle D^{(*)}|J\cdot a|B\rangle|^2}{4m_B E_{D^{(*)}}} < \frac{1}{2\pi i}\int_C \mathrm{d}\epsilon\, W_\Delta(\epsilon)[a^{*\mu} T_{\mu\nu} a^\nu]. \tag{12}$$

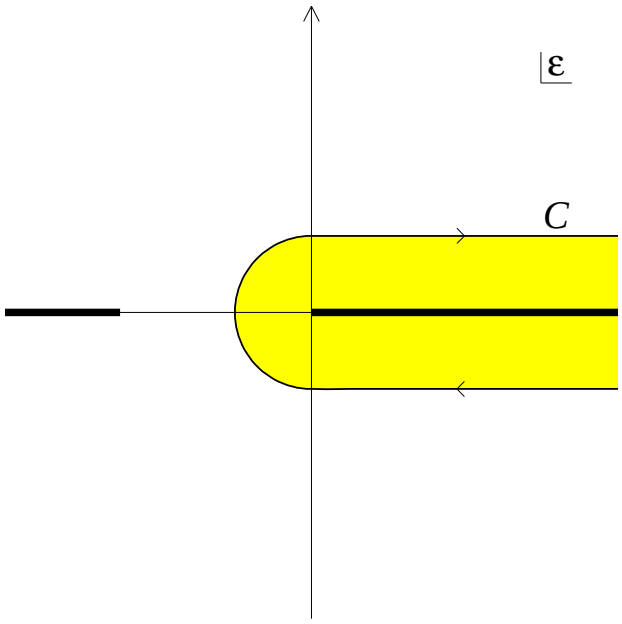

FIGURE 1. The integration contour C in the complex ϵ plane. The cuts extend to $\mathrm{Re}\,\epsilon \to \pm\infty$.

In eq. (12) a sum over D^* polarizations is understood. It is also possible to derive a lower bound if some model dependent assumptions concerning the spectrum of final states X are made.

A possible set of weight functions is [6],

$$W_\Delta^{(n)}(\epsilon) = \frac{\Delta^{2n}}{\epsilon^{2n} + \Delta^{2n}}\,, \qquad (n = 2, 3, \ldots). \tag{13}$$

They satisfy the following properties: (i) W_Δ is positive along the cut so that every term in the sum over X on the hadron side of the sum rule is positive; (ii) $W_\Delta(0) = 1$; (iii) W_Δ is flat near $\epsilon = 0$; and (iv) W_Δ falls off rapidly for $\epsilon > \Delta$. For values of n of order unity all the poles of $W_\Delta^{(n)}$ lie at a distance of order Δ away from the physical cut. As $n \to \infty$, $W_\Delta^{(n)}$ approaches $\theta(\Delta - \epsilon)$ for $\epsilon > 0$, which corresponds to summing over all final hadronic resonances up to excitation energy Δ with equal weight. In this limit the poles of $W_\Delta^{(n)}$ approach the cut, and the contour C is forced to pinch the cut at $\epsilon = \Delta$. Then the evaluation of the contour integrals using perturbative QCD relies on local duality at the scale Δ. In practice, for $n > 3$ the results obtained are very close to those for $n = \infty$ and for the remainder of this lecture I will only quote results obtained from the weight $W_\Delta^{(\infty)}(\epsilon) = \theta(\Delta - \epsilon)$.

III APPLICATION OF SUM RULES AT ZERO RECOIL

The sum rule bound in eq. (12) is made explicit by using the operator product expansion and perturbative QCD to evaluate the right-hand side. The most important kinematic point is the zero recoil point where $\vec{q} = 0$. Choosing a to be a spatial vector $a = (0, \hat{n})$ and averaging over directions of the unit vector $\hat{n}$, we obtain for the axial vector current

$$|\mathcal{F}_{B\to D^*}(1)|^2 \le \eta_A^2 - \frac{\lambda_2}{m_c^2} + \left(\frac{\lambda_1 + 3\lambda_2}{4}\right)\left(\frac{1}{m_c^2} + \frac{1}{m_b^2} + \frac{2}{3m_c m_b}\right) + \frac{\alpha_s(\Delta)}{\pi} X_{AA}(\Delta) + \frac{\alpha_s^2(\Delta)}{\pi^2}\beta_0 Y_{AA}(\Delta), \tag{14}$$

and for the vector current

$$0 \le \frac{\lambda_2}{m_c^2} - \left(\frac{\lambda_1 + 3\lambda_2}{4}\right)\left(\frac{1}{m_c^2} + \frac{1}{m_b^2} - \frac{2}{3m_c m_b}\right) + \frac{\alpha_s(\Delta)}{\pi} X_{VV}(\Delta) + \frac{\alpha_s^2(\Delta)}{\pi^2}\beta_0 Y_{VV}(\Delta). \tag{15}$$

Eqs. (14) and (15) include terms of order $\Lambda_{\rm QCD}^2/m_c^2$ coming from dimension five operators in the operator product expansion for the time ordered product of currents. The coefficients of these operators are evaluated at tree level. Also included is the contribution from the dimension 3 operator $\bar{h}_v^{(b)}\Gamma h_v^{(b)}$ evaluated to order $\alpha_s^2\beta_0$. There are two distinct sources of perturbative QCD corrections. Those in η_A correspond to a final state X_c that at the parton level is a single charm quark. These terms are independent of Δ and come from matching of the axial vector current onto its HQET counterpart, i.e., $A^\nu = \eta_A \bar{h}_v^{(b)}\gamma^\nu\gamma_5 h_v^{(c)}$. The part of the QCD correction involving X_{AA}, Y_{AA}, X_{VV} and Y_{VV}, comes at the parton level from states with a charm quark and a gluon or even more partons. These corrections depend on Δ. Since Δ is the cut off on the invariant mass of the final hadronic states it seems most natural to write these terms as a power series in $\alpha_s(\Delta)$. If one used $\alpha_s(\mu)$ with μ much different from Δ the coefficients Y_{AA} and Y_{VV} would contain large logarithms of Δ/μ. Analytic expressions for the order α_s corrections are known [6]

$$X_{AA}(\Delta) = \frac{\Delta(\Delta + 2m_c)[2(\Delta + m_c)^2 - 2m_b^2 - (m_b + m_c)^2]}{18m_b^2(\Delta + m_c)^2} + \frac{3m_b^2 + 2m_b m_c - m_c^2}{9m_b^2}\ln\left(\frac{\Delta + m_c}{m_c}\right), \tag{16}$$

$$X_{VV}(\Delta) = \frac{\Delta(\Delta + 2m_c)[2(\Delta + m_c)^2 - 2m_b^2 - (m_b - m_c)^2]}{18m_b^2(\Delta + m_c)^2} + \frac{3m_b^2 - 2m_b m_c - m_c^2}{9m_b^2}\ln\left(\frac{\Delta + m_c}{m_c}\right). \tag{17}$$

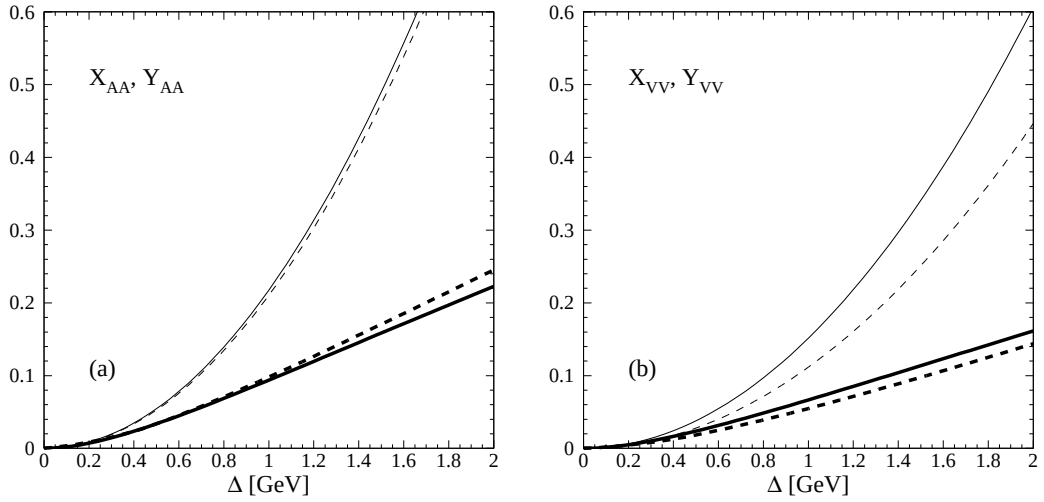

FIGURE 2. $X(\Delta)$ and $Y(\Delta)$ for the a) axial, and b) vector coefficients. Thick solid lines are X while thick dashed lines are Y. The thin solid and dashed lines are X and Y to order $\Delta^2/m_{c,b}^2$.

For small Δ, X_{AA} and X_{VV} are of order $\Delta^2/m_{c,b}^2$; however, even when $\Delta = 1\,\mathrm{GeV}$, terms higher order in $\Delta/m_{c,b}$ are important (the small Δ approximation to X_{AA} and X_{VV} was calculated in Ref. [4]). The values of Y_{AA} and Y_{VV} have been determined numerically [6]. In Fig. 2, X_{AA}, Y_{AA}, X_{VV}, and Y_{VV} are plotted as functions of Δ in the region $\Delta < 2\,\mathrm{GeV}$. The values of Y are quite close to X in this region.

The vector current sum rule bound in eq. (15) implies a bound on λ_1. This bound is strongest for $m_c \gg m_b \gg \Delta$. In that limit it becomes [4,6]

$$\lambda_1 \le -3\lambda_2 + \frac{\alpha_s(\Delta)}{\pi}\Delta^2\left(\frac{4}{3}\right) + \frac{\alpha_s^2(\Delta)}{\pi^2}\beta_0\Delta^2\left(\frac{13}{9} - \frac{2\ln 2}{3}\right). \tag{18}$$

The parameter Δ must be chosen large enough that perturbative QCD is meaningful. However the bounds on λ_1 and $|\mathcal{F}_{B\to D^*}|^2$ become stronger the smaller the value of Δ. The smallest value of Δ for which one can imagine using perturbative QCD is $1\,\mathrm{GeV}$. Using $\Delta = 1\,\mathrm{GeV}$, $\alpha_s(1\mathrm{GeV}) = 0.45$, $\lambda_2 = 0.12\,\mathrm{GeV}^2$, eq. (18) implies

$$\lambda_1 \le (-0.36 + 0.19 + 0.20)\,\mathrm{GeV}^2. \tag{19}$$

The three terms on the right-hand side of eq. (19) correspond respectively to the contribution of λ_2, the perturbative part of order $\alpha_s(\Delta)\Delta^2/\pi$, and the perturbative part of order $[\alpha_s(\Delta)/\pi]^2\Delta^2$. Notice that with $\Delta = 1\,\mathrm{GeV}$ the α_s^2 term is as large as the order α_s term. It may be a mistake to conclude from this that $\Delta = 1\,\mathrm{GeV}$ is too low for QCD perturbation theory to be meaningful. It has been conjectured that λ_1 has a renormalon ambiguity of order Λ_{QCD}^2

(one does not see this from the usual sum of bubble graphs) [22]. Even though the renormalon ambiguity arises from large orders of perturbation theory, it is possible that the bad behavior of the first few terms in the perturbative series presented in eq. (18) is a reflection of this uncertainty.

In this lecture the matrix element λ_1 is defined using dimensional regularization and $\overline{\rm MS}$ subtraction. If λ_1 has a renormalon ambiguity (of order $\Lambda_{\rm QCD}^2$), the perturbative QCD series that relates it to a physical quantity, for example computed in lattice QCD, is not Borel summable. However, there is no evidence that this is a serious problem. Whenever λ_1 occurs in an expression for some measurable quantity, e.g., the bound on $|\mathcal{F}_{B\to D^*}(1)|^2$, there is another perturbative series that when combined with the series in λ_1 (e.g., from matching onto lattice QCD) probably has no renormalon ambiguity (of order $\Lambda_{\rm QCD}^2$) [23].

Next consider the bound on $|\mathcal{F}_{B\to D^*}(1)|^2$ in eq. (14). We can eliminate λ_1 from it by combining (14) and (15). This gives

$$\begin{aligned}|\mathcal{F}_{B\to D^*}(1)|^2 \le \eta_A^2 - \frac{\lambda_2}{m_c^2} + \frac{\alpha_s(\Delta)}{\pi}\left[X_{AA}(\Delta) + \frac{1}{3}\left(\frac{\Delta^2}{m_c^2}+\frac{\Delta^2}{m_b^2}+\frac{2\Delta^2}{3m_cm_b}\right)\right] \\ + \frac{\alpha_s^2(\Delta)}{\pi^2}\beta_0\left[Y_{AA}(\Delta) + \left(\frac{13}{36}-\frac{\ln 2}{6}\right)\left(\frac{\Delta^2}{m_c^2}+\frac{\Delta^2}{m_b^2}+\frac{2\Delta^2}{3m_cm_b}\right)\right].\end{aligned} \tag{20}$$

Neglecting the nonperturbative correction factor of $-\lambda_2/m_c^2$ and again using $\Delta = 1\,\text{GeV}$, the above bound is

$$\begin{aligned}|\mathcal{F}_{B\to D^*}(1)|^2 &\le 1 - 0.074 - 0.020 \\ &\quad + 0.044 + 0.046 \\ &= 1 - 0.030 + 0.026.\end{aligned} \tag{21}$$

Here we used $m_c = 1.4\,\text{GeV}$, $m_b = 4.8\,\text{GeV}$, $\alpha_s(\sqrt{m_cm_b}) = 0.28$, $\alpha_s(1\,\text{GeV}) = 0.45$, and $\beta_0 = 9$. The first row is the perturbative expansion of η_A^2, the second row is the order $\alpha_s(\Delta)$ and order $\alpha_s(\Delta)^2$ terms, and the third row sums the columns. There is a renormalon ambiguity of order $\Lambda_{\rm QCD}^2/m_{c,b}^2$ that cancels between the perturbative series for η_A^2 and the series in $\alpha_s(\Delta)$. This bound on the physical quantity $|\mathcal{F}_{B\to D^*}(1)|^2$ is not very strong (even when the factor of $-\lambda_2/m_c^2$ is included), and furthermore the third row of eq. (21) seems to indicate that with $\Delta = 1\,\text{GeV}$ QCD perturbation theory is not very well behaved. However, this does not mean that the sum rule for $|\mathcal{F}_{B\to D^*}(1)|^2$ in eq. (14) is not useful. Consider the perturbative part of eq. (14), neglecting for now both the terms of order $\lambda_1/m_{c,b}^2$ and $\lambda_2/m_{c,b}^2$. Numerically, with $\Delta = 1\,\text{GeV}$, this gives

$$\begin{aligned}|\mathcal{F}_{B\to D^*}(1)|^2 &\le 1 - 0.074 - 0.020 \\ &\quad + 0.013 + 0.017 \\ &= 1 - 0.061 - 0.003.\end{aligned} \tag{22}$$

Again, the first row is the perturbative expansion of η_A^2 and the second row are the terms of order $\alpha_s(\Delta)$ and $\alpha_s^2(\Delta)$. The third row of eq. (22) does not indicate that there is any breakdown of QCD perturbation theory. If λ_1 can be determined experimentally from, for example, the electron spectrum in inclusive semileptonic B-decay then the sum rule in eq. (14) may lead to an important constraint. For example, with $\Delta = 1\,\mathrm{GeV}$ and $\lambda_1 = -0.2\,\mathrm{GeV}^2$, eq. (14) implies the bound

$$|F_{B\to D^*}(1)|^2 \leq 0.90, \tag{23}$$

which is smaller than $\eta_A^2 = 0.91$.

IV THE LEPTON ENERGY SPECTRUM AND THE PARAMETERS λ_1, $\bar{\Lambda}$

The CLEO collaboration has measured the lepton energy spectrum for inclusive $B \to X\ell\bar{\nu}_e$ decay, both demanding only one charged lepton (single tagged data) and two charged leptons (double tagged sample) [24,25]. In the double tagged sample the charge of the high momentum lepton determines whether the other lepton comes from a semileptonic B decay (primary lepton) or the semileptonic decay of a D-meson (secondary lepton). The single tagged sample is presented in 50 MeV bins while the double tagged data is presented in 100 MeV bins. The single tagged sample has much higher statistics, but is significantly contaminated by secondaries below $E_\ell = 1.5\,\mathrm{GeV}$.

The operator product expansion for semileptonic B decay does not reproduce the physical lepton spectrum point by point near the maximal electron energy. Near the endpoint, comparison of theory with data can only be made after smearing or integrating over a large enough region. The minimal size of this region has been estimated to be about 500 MeV. As was mentioned in the introduction, the theoretical prediction for the lepton energy spectrum depends on λ_1 and $\bar{\Lambda}$, so we can try to use the data to determine these quantities. We want to consider observables sensitive to $\bar{\Lambda}$ and λ_1, but we also want deviations from the b-quark decay rate to be small enough so that contributions from even higher dimension operators in the operator product expansion are small. Ref. [26] uses R_1 and R_2, where

$$R_1 = \frac{\int_{1.5\,\mathrm{GeV}} (\mathrm{d}\Gamma/\mathrm{d}E_\ell) E_\ell \,\mathrm{d}E_\ell}{\int_{1.5\,\mathrm{GeV}} (\mathrm{d}\Gamma/\mathrm{d}E_\ell)\,\mathrm{d}E_\ell}, \tag{24}$$

and

$$R_2 = \frac{\int_{1.7\,\mathrm{GeV}} (\mathrm{d}\Gamma/\mathrm{d}E_\ell)\,\mathrm{d}E_\ell}{\int_{1.5\,\mathrm{GeV}} (\mathrm{d}\Gamma/\mathrm{d}E_\ell)\,\mathrm{d}E_\ell}. \tag{25}$$

Here E_ℓ denotes the lepton energy. The variable R_1 has dimensions of mass and values for it will be given in GeV. Ratios are considered so that $|V_{cb}|$ cancels out. Before comparing the experimental data with theoretical predictions derived from the operator product expansion and QCD perturbation theory, it is necessary to include electromagnetic corrections and effects of the boost to the laboratory frame. This gives

$$\begin{aligned} R_1 = {} & 1.8059 - 0.309\left(\frac{\bar\Lambda}{\bar m_B}\right) - 0.35\left(\frac{\bar\Lambda}{\bar m_B}\right)^2 - 2.32\left(\frac{\lambda_1}{\bar m_B^2}\right) - 3.96\left(\frac{\lambda_2}{\bar m_B^2}\right) \\ & - \frac{\alpha_s}{\pi}\left(0.035 + 0.07\frac{\bar\Lambda}{\bar m_B}\right) + \left|\frac{V_{ub}}{V_{cb}}\right|^2\left(1.33 - 10.3\frac{\bar\Lambda}{\bar m_B}\right) \\ & - \left(0.0041 - 0.004\frac{\bar\Lambda}{\bar m_B}\right) + \left(0.0062 + 0.002\frac{\bar\Lambda}{\bar m_B}\right), \end{aligned} \tag{26}$$

and

$$\begin{aligned} R_2 = {} & 0.6581 - 0.315\left(\frac{\bar\Lambda}{\bar m_B}\right) - 0.68\left(\frac{\bar\Lambda}{\bar m_B}\right)^2 - 1.65\left(\frac{\lambda_1}{\bar m_B^2}\right) - 4.94\left(\frac{\lambda_2}{\bar m_B^2}\right) \\ & - \frac{\alpha_s}{\pi}\left(0.039 + 0.18\frac{\bar\Lambda}{\bar m_B}\right) + \left|\frac{V_{ub}}{V_{cb}}\right|^2\left(0.87 - 3.8\frac{\bar\Lambda}{\bar m_B}\right) \\ & - \left(0.0073 + 0.005\frac{\bar\Lambda}{\bar m_B}\right) + \left(0.0021 + 0.003\frac{\bar\Lambda}{\bar m_B}\right). \end{aligned} \tag{27}$$

In eqs. (26) and (27) the charm and bottom quark masses have been expressed in terms of $\bar m_B$, $\bar m_D$, $\bar\Lambda$, λ_1, and λ_2 using eq. (3), which is why $\bar\Lambda$ occurs in these formulas. The last two terms in eqs. (26) and (27) are from electromagnetic radiative corrections and from the boost to the laboratory frame respectively. The experimental values for R_1 and R_2 are $R_1 = 1.7831\,\mathrm{GeV}$ and $R_2 = 0.6159$. These were obtained from the single tagged data with a correction for the secondary leptons obtained from the double tagged sample. For R_1 this correction is $0.0001\,\mathrm{GeV}$ and for R_2 it is 0.0051. Comparing experiment with eqs. (26) and (27) gives the central values $\bar\Lambda = 0.39 \pm 0.11\,\mathrm{GeV}$ and $\lambda_1 = -0.19 \pm 0.10\,\mathrm{GeV}^2$. Fig. 3 shows the one sigma bands on the allowed values of $\bar\Lambda$ and λ_1 from R_1 and R_2. The narrower band corresponds to the R_1 constraint. The shaded ellipse is the one sigma allowed region for $\bar\Lambda$ and λ_1 including correlations between R_1 and R_2. The errors included in this analysis are just the statistical ones. An analysis of systematic errors has not been performed. However, they are only weakly energy dependent for $E_\ell \geq 1.5\,\mathrm{GeV}$ and it is hoped that for $R_{1,2}$ systematic errors are smaller than the statistical ones. Note that the bands from R_1 and R_2 are almost parallel, so even small corrections can significantly change the central values for $\bar\Lambda$ and λ_1 obtained from Fig. 3.

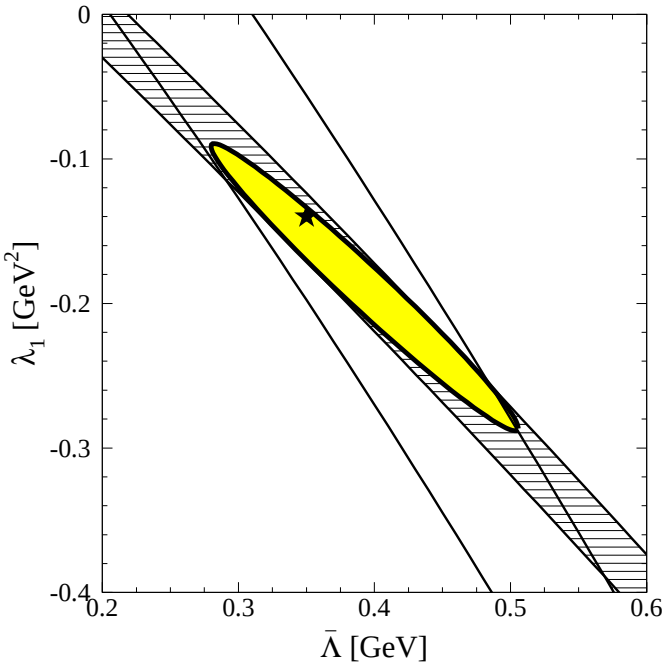

FIGURE 3. Allowed regions in the $\bar{\Lambda} - \lambda_1$ plane for R_1 and R_2. The bands represent the 1σ statistical errors, while the ellipse is the allowed region taking correlations into account. The star denotes where the order $\Lambda^3_{\rm QCD}/\bar{m}^3_B$ corrections discussed in the text would shift the center of the ellipse.

One such set of corrections comes from higher dimension operator in the operator product expansion. At order $\Lambda^3_{\rm QCD}/\bar{m}^3_B$ new terms occur characterized by two matrix elements ρ_1 and ρ_2 and two time ordered products. ρ_1 can be estimated by factorization, $\rho_1 = (2\pi\alpha_s/9) m_B f_B^2 \approx (300\,{\rm MeV})^3$, and ρ_2 is expected to be small [4]. Neglecting ρ_2 and the time ordered products gives the following order $\Lambda^3_{\rm QCD}/\bar{m}^3_B$ corrections to R_1 and R_2,

$$\begin{aligned}
\delta R_1 &= -(0.4\bar{\Lambda}^3 + 5.7\bar{\Lambda}\lambda_1 + 6.8\bar{\Lambda}\lambda_2 + 7.7\rho_1)/\bar{m}^3_B, \\
\delta R_2 &= -(1.5\bar{\Lambda}^3 + 7.1\bar{\Lambda}\lambda_1 + 17.5\bar{\Lambda}\lambda_2 + 1.8\rho_1)/\bar{m}^3_B.
\end{aligned} \tag{28}$$

Including these corrections shifts the central values for $\bar{\Lambda}$ and λ_1 to the location $\bar{\Lambda} = 0.35\,{\rm GeV}$ and $\lambda_1 = -0.15\,{\rm GeV}^2$ marked by the star in Fig. 3. For a more complete discussion of the order $\Lambda^3_{\rm QCD}/\bar{m}^3_B$ corrections, see Ref. [27].

The bands in Fig. 3 were determined using $|V_{ub}/V_{cb}| = 0.08$. This value is model dependent. If $|V_{ub}/V_{cb}| = 0.10$ is used then the central values shift to $\bar{\Lambda} = 0.42\,{\rm GeV}$ and $\lambda_1 = -0.19\,{\rm GeV}^2$. In Fig. 3, $\alpha_s = 0.22$ was used corresponding to a subtraction point near m_b. With $\alpha_s = 0.35$ the central values shift to $\bar{\Lambda} = 0.36\,{\rm GeV}$ and $\lambda_1 = -0.18\,{\rm GeV}^2$.

Theoretical uncertainty in this determination of $\bar{\Lambda}$ and λ_1 originate from the reliability of quark hadron duality at the limits of integration defining $R_{1,2}$,

order $\Lambda^3_{\rm QCD}/\bar{m}^3_B$ corrections, and higher order perturbative QCD corrections. Recently the order $\alpha_s^2\beta_0$ terms in R_1 and R_2 have been computed [28]. They give corrections $\delta R_1 = -0.082\alpha_s^2\beta_0/\pi^2$ and $\delta R_2 = -0.098\alpha_s^2\beta_0/\pi^2$, moving the central values to $\bar{\Lambda} = 0.33\,{\rm GeV}$ and $\lambda_1 = -0.17\,{\rm GeV}^2$. Concerning duality, note that the lower limits on the lepton energy $E_\ell \geq 1.5\,{\rm GeV}$ and $E_\ell \geq 1.7\,{\rm GeV}$ used in $R_{1,2}$ correspond to summing over hadronic states X with masses less than 3.6 GeV and 3.3 GeV respectively. Changing the lower limit in the numerator of R_2 to 1.8 GeV leads to central values $\bar{\Lambda} = 0.47\,{\rm GeV}$ and $\lambda_1 = -0.26\,{\rm GeV}^2$. The plot in Fig. 3 uses electron data only. Using the muon sample instead gives compatible central values of $\bar{\Lambda} = 0.43\,{\rm GeV}$ and $\lambda_1 = -0.21\,{\rm GeV}^2$.

It would be nice to have another constraint on λ_1 and $\bar{\Lambda}$ that would be less parallel than R_1 and R_2 are. This can be provided by the photon spectrum in inclusive $B \to X_s\gamma$ decay [29] which, when the data improves, will give a band almost parallel to the λ_1 axis of Fig. 3. Lattice QCD can also be used to determine λ_1 and $\bar{\Lambda}$, although for λ_1 there are serious difficulties coming from mixing with the lower dimension operator $\bar{h}_v^{(b)} h_v^{(b)}$ [30]. This mixing does not occur in the continuum if dimensional regularization with $\overline{\rm MS}$ subtraction is used.

V CONCLUDING REMARKS

In this lecture I have reviewed the derivation of B-decay sum rules, discussed the perturbative QCD corrections, and reviewed the status of the determination of the nonperturbative QCD matrix element λ_1 that occurs in the sum rules.

If the contribution of the lowest lying excited states X on the right-hand side of eq. (11) were known then this would imply a better bound on the ground state matrix elements. The lowest lying excited states are nonresonant $D^{(*)}\pi$. Their contribution, for low $D^{(*)}\pi$ invariant mass, is calculable [4] in terms of the one coupling constant, g, of heavy hadron chiral perturbation theory [31]. This coupling also determines the D^* width, $\Gamma(D^{*+} \to D^0\pi^+) = (g^2/6\pi f_\pi^2)|\vec{p}_\pi|^3$ (for the neutral pion mode there is an additional factor of 1/2). Unfortunately at the present time there is only a limit on the D^* width and hence an upper bound on g. A measurement of the D^* width would give a direct determination of this coupling. Then we would know the contribution of these nonresonant states to the sum rules. (Determining g from various D^* and D_s^* branching ratios is discussed in Ref. [32]). Higher in mass is the $s_\ell^{\pi\ell} = \frac{3}{2}^+$ doublet of excited charmed mesons $D_1(2420)$ and $D_2^*(2460)$. These states are narrow with widths around 20 MeV. A doublet with $s_\ell^{\pi\ell} = \frac{1}{2}^+$ quantum numbers is expected to also exist, but these states are thought to be quite broad (i.e., widths greater than 100 MeV). Very recently the contribution of these excited charmed mesons to the sum rules has been discussed [33].

Perturbative QCD corrections to the sum rules have been calculated to order $\alpha_s^2\beta_0$. It is important to improve this to a full order α_s^2 calculation. Finally, it is interesting to note that B-decay sum rules may also be important for the $b \to u$ transition, giving valuable information on exclusive $B \to \pi\ell\bar{\nu}_\ell$ or $B \to \rho\ell\bar{\nu}_\ell$ form factors [8]. At this time perturbative corrections to these $b \to u$ transition sum rules have not been computed.
